

Sales Bot MVP

Product Ideas, Flow & Architecture

This document compiles the core concepts, user workflows, and technical considerations for the proposed Sales Bot Minimum Viable Product (MVP) discussed in the design phase.

1. Core Concept & Objectives

The primary goal of the MVP is to create an intelligent, context-aware chatbot platform that allows users to upload specific datasets and interact with an AI tailored strictly to that information. The bot must be capable of answering questions accurately based on the provided data, compiling information efficiently, and outputting the results in a well-structured text format.

Ultimate MVP Goal: Build a bot that flawlessly understands fed data, answers queries based exclusively on that data, and cleanly compiles the outputs into properly arranged text formats.

2. Primary User Journey: Context-Aware Bot

The main workflow is designed around creating isolated "contexts" where a bot operates with specific knowledge bases.

Step 1: Authentication & Login

Users begin at a standard interface requiring a username and password. Credentials and session data are securely stored and verified against the core database.

Step 2: Dashboard & Context Creation

Upon successful login, the user accesses the main dashboard. They are presented with an option to "**Add Bot**" or "**Add Context**". Selecting this creates a new, isolated context window dedicated exclusively to a specific topic or dataset.

Step 3: Data Ingestion ("Feed Data")

Within the newly created context, the user utilizes the **"Feed Data"** functionality. They input the specific information they want the bot to learn. The AI processes and understands this specific dataset, locking its knowledge base to this context.

Step 4: Interaction & Updating

Once the context is established and data is fed, the chat interface unlocks. When users return to this specific context later, they have two primary options:

- **Chat with Bot:** Converse with the AI based on the existing stored data.
- **Feed New Data:** Update the context by feeding new or revised information. The bot seamlessly updates its understanding and subsequent responses will reflect the newly added data.

3. Secondary Feature: Discussion Bot

Alongside the strictly context-aware sales/data bot, the platform will feature a secondary "Discussion Bot" intended for general research, brainstorming, and everyday AI assistance.

- **Temporary Sessions:** Unlike the primary bot, the Discussion Bot does not store data long-term. Chats are temporary and designed for one-off research tasks.
- **Cost Optimization (Token Catching):** To prevent excessive API credit usage during long research sessions, the system will implement a token management strategy. The bot will automatically "catch" or summarize context every 10,000 to 100,000 tokens, maintaining conversational awareness without ballooning the context window costs.

4. Output & Deliverables

A critical requirement for the MVP is how it handles the final output. The system must not only converse but also act as a compiler of the fed data. The final output must be:

- Strictly derived from the given context data.
- Presented in a highly readable, proper text format (with the potential to expand into presentations or PDFs in future iterations).
- Arranged logically based on the user's synthesis requests during the chat.
